Not illustrated. 1814 Excerpt: ...all the molecules of which the density is the same; therefore p is nothing relative to the surfaces of the laminae of the fluid mass in which the density is constant; and we shall have by relation to these surfaces It therefore follows, that the resultant of the forces which act upon each fluid molecule, is in the state of equilibrium perpendicular to the surfaces of these laminae; which have been named on that account (*couches de niveau*) laminae of level. This condition is always fulfilled if the fluid is homogeneous and incompressible; because in this case the laminae to which this resultant is perpendicular are all of the same density. In the case of the equilibrium of an elastic fluid, the pressure is found by experiment to vary as the density, consequently p may be supposed equal to ag . If $p=ag$ then $f=$ ---, let this value of f be substituted in the equation $dp=-1$ $fdip$ and it will give $adp=-pdtp$, consequently $d.\log.p=-.dp$. If the fluid be homogeneal and of the same temperature, a is constant and the equation possible. By integration we shall have $\log.p=---+Iog.c$, or $p=c.ea$, c being a constant quantity, and e the base of the system of logarithms which has unity for its modulus. As this value of p and conse P quently that of $s=r$ are functions of the sole variable p , th« For the equilibrium of an homogeneous fluid mass, the exterior surface of which is free, and covers a solid mass fixed and of any figure whatever; it is therefore pressure and the density will be the same for all the extent of each lamina of level as in the case of heterogeneal fluids; the densities of the different lamina; are determined by the equation 9 a i-a If in an homogeneal fluid the temperature be no't the same throughout the mass, the quantity a' will not be constant; let t deno...
